## Parallel algorithms for scientific applications

Michael A. G. Aïvázis

California Institute of Technology

Spring 2012

- ▶ string literals

<i>Literal</i>	<i>Description</i>
'Hello'	single quotes
"Hello",	double quotes
"It's embedded"	mix and match
'''Hello''', """Hello"""	triple quotes – extend over multiple lines

- ▶ strings are immutable ordered sequences of unicode characters

- ▶ no `char` type: `'a'` is a string with one character
- ▶ native support for all code pages

- ▶ common operations: given the strings  $s_i$ :

<i>Expression</i>	<i>Description</i>
<code>s1+s2, s*4</code>	concatenation, repetition
<code>s[3], s[3:4]</code>	indexing, slicing
<code>len(s)</code>	length
<code>'H' in s</code>	membership
<code>for x in s</code>	iteration

# String coercions

- ▶ all objects are representable as strings
- ▶ coercion can be triggered explicitly
  - ▶ using the `str` constructor
  - ▶ using the `repr` built-in function
- ▶ strings have a powerful formatting method:

```
1 'temperature={:+13.4f}, pressure={:13.4f}'.format(T, P)
```

- ▶ more details after we go over the rules for function calls

- ▶ tuples are immutable ordered inhomogeneous sequences of objects

<i>Literal</i>	<i>Description</i>
<code>()</code>	the empty tuple
<code>(1,)</code>	a tuple with one item
<code>(1, 2, 3, 4)</code>	a longer tuple
<code>(1, 'Hello', 'world')</code>	tuple elements don't have to be the same type
<code>(1, 2, ('Hello', 'world'), 4)</code>	tuples nest arbitrarily deeply

- ▶ common operations:

<i>Expression</i>	<i>Description</i>
<code>t1+t2, t*4</code>	concatenation, repetition
<code>t[3], t[3:4]</code>	indexing, slicing
<code>len(t)</code>	length
<code>x in t</code>	membership
<code>for x in t</code>	iteration

- lists are mutable ordered inhomogeneous sequences of objects

<i>Literal</i>	<i>Description</i>
<code>[]</code>	the empty list
<code>[1]</code>	a list with one item
<code>[1, 2, 3, 4]</code>	a longer list
<code>[1, 'Hello', 'world']</code>	list elements don't have to be the same type
<code>[1, 2, ['Hello', 'world'], 4]</code>	lists nest arbitrarily deeply

- common operations:

<i>Expression</i>	<i>Description</i>
<code>l1+l2, l*4</code>	concatenation, repetition
<code>len(l), x in l, for x in l</code>	length, membership, iteration
<code>l[3], l[3:4]</code>	indexing, slicing
<code>del l[3], l[3:7]=[]</code>	shrink
<code>l[3:7]=[1, 2]</code>	slice assignment
<code>l.append(1)</code>	add to the end of the list

- sets are mutable unordered inhomogeneous containers of objects

<i>Literal</i>	<i>Description</i>
<code>set()</code>	the empty set
<code>{1}</code>	a set with one item
<code>{1, 2, 3, 4}</code>	a longer set
<code>{1, 'Hello', 'world'}</code>	set elements don't have to be the same type

- common operations:

<i>Expression</i>	<i>Description</i>
<code>s1   s2</code>	union
<code>s1 &amp; s2</code>	intersection
<code>s1 - s2, s1 ^ s2</code>	difference, symmetric difference
<code>len(s), x in s, for x in s</code>	length, membership, iteration
<code>s.add(x)</code>	add
<code>s.discard(x)</code>	remove if present
<code>s.remove(x)</code>	remove; raise <code>KeyError</code> if not present

# Dictionaries

- ▶ dictionaries are mutable inhomogeneous associative maps

<i>Literal</i>	<i>Description</i>
<code>{}</code>	the empty dictionary
<code>{'first': 'Guido', 'last': 'van Rossum'}</code>	a dictionary with two items

- ▶ dictionary keys must be *hashable*; dictionary values may be of any type
- ▶ common operations

<i>Expression</i>	<i>Description</i>
<code>d['first'] = 'Guido'</code>	make an association
<code>d['first']</code>	value retrieval
<code>d.get('first'), d.get('first', default='')</code>	raise <code>KeyError</code> if key not present value retrieval
<code>len(d)</code>	the number of keys
<code>x in d</code>	key presence
<code>d.keys(), d.values(), d.items()</code>	views of the dictionary contents
